Goals for Lecture

the key concepts to understand are the following

- approaches to determining the structure of an SCFG grammar
- the task of searching for sequences that “match” a given RNA structure

Where do we get a grammar?

1. from a canonical secondary structure
2. through an iterative, refinement process
3. alternatively, use a simple, generic one

1. Deriving a Grammar from a Secondary Structure

given a structure

can construct a simple grammar characterizing it

$$s \rightarrow C s_1 G$$

$$s_1 \rightarrow A s_2 U$$

$$s_2 \rightarrow b_1 b_2 b_3$$

$$b_1 \rightarrow U$$

$$b_2 \rightarrow U$$

$$b_3 \rightarrow C$$

can add productions to allow for variation

$$s \rightarrow U s_1 A$$

$$s \rightarrow A s_1 U$$

$$s \rightarrow G s_1 C$$

base pair substitutions

$$s_1 \rightarrow s_1 A$$

insertions

$$b_2 \rightarrow A$$

$$b_2 \rightarrow C$$

$$b_2 \rightarrow G$$

single base substitutions

2. Deriving a Grammar Through an Iterative Process

- consider the approach used by Eddy & Durbin to learn an SCFG model of tRNAs

Figure from Eddy & Durbin, *Nucleic Acids Research*, 22(11):2079-2088, 1994.

Eddy & Durbin: Model Construction Step

- given multiple alignment, compute mutual information between pairs of positions

A

$$M(i, j) = \sum_{x_i, x_j} f_{x_i x_j} \log_2 \frac{f_{x_i x_j}}{f_{x_i} f_{x_j}}$$

frequency of x_i in column i

joint frequency of x_i in column i and x_j in column j

Eddy & Durbin: Model Construction Step

- use a DP like Nussinov to find folded structure that maximizes mutual information

A

$$\gamma(i, j) = \max \begin{cases} \gamma(i+1, j) \\ \gamma(i, j-1) \\ \gamma(i+1, j-1) + M(i, j) \\ \max_{i < k < j} [\gamma(i, k) + \gamma(k+1, j)] \end{cases}$$

- then derive grammar from this structure

Figure from Voß, *Nucleic Acids Research*, 34:5471-5481, 2006.

3. Using a Simple, Generic Grammar

- a grammar that could characterize almost any RNA structure

$$s \rightarrow C s G \mid G s C \mid A s U \mid U s A$$

$$s \rightarrow C s \mid G s \mid A s \mid U s$$

$$s \rightarrow s G \mid s C \mid s U \mid s A$$

$$s \rightarrow G \mid C \mid U \mid A$$

$$s \rightarrow s s$$

Searching Sequence for a Secondary Structure

Given

- a single RNA sequence with its secondary structure
- another RNA query sequence

ACGGCUUCGGCCUGGCGAGACCC

Determine if the query sequence has the “same” secondary structure

Searching Sequence for a Secondary Structure

- this is analogous to pairwise alignment with primary sequences
- we take into account substitutions, insertions/deletions, and base-pair substitutions

ACGGCUUCGGCCUGGCGAGACCC

Deriving a Grammar from Secondary Structure

given a structure

can construct a simple grammar characterizing it

$$s \rightarrow C s_1 G$$

$$s_1 \rightarrow A s_2 U$$

$$s_2 \rightarrow b_1 l_1$$

$$l_1 \rightarrow b_2 b_3$$

$$b_1 \rightarrow U$$

$$b_2 \rightarrow U$$

$$b_3 \rightarrow C$$

can add productions to allow for variation

$$s \rightarrow U s_1 A$$

$$s \rightarrow A s_1 U$$

$$s \rightarrow G s_1 C$$

base pair substitutions

$$s_1 \rightarrow s_1 A$$

insertions

$$b_2 \rightarrow A$$

$$b_2 \rightarrow C$$

$$b_2 \rightarrow G$$

single base substitutions

The RIBOSUM Matrices [Klein & Eddy]

observed frequency of i aligned
to j in homologous RNAs

background frequency of i

$$s_{ij} = \log_2 \frac{f_{ij}}{g_i g_j}$$

[illegible]

$$s'_{ijkl} = \log_2 \frac{f'_{ijkl}}{g_i g_j g_k g_l}$$

observed frequency of two base pairs $i-j$ and $k-l$ aligned to each other in homologous RNAs

Setting the Parameters in the Grammar

- Infer parameters from the RIBOSUM matrices (taking into account the latter are log-odds scores)

RSEARCH: Searching Sequence for a Secondary Structure

[Klein & Eddy, *BMC Bioinformatics* 2003]

- the RSEARCH algorithm implements this idea
- but uses a somewhat different SCFG formulation – covariance models (see section 10.3 in Durbin et al.)

6S RNA Secondary Structure

An RSEARCH Case Study

- finding 6S genes in bacterial genomes
 - E. coli 6S as the query structure
 - searched 14 other genomes with known 6S genes
 - ~ 5,000 intergenic sequences on average
 - the top-scoring RSEARCH hit in all 14 genomes was the known 6S gene

Summary of RNA Analysis Tasks

- given a sequence, predict its secondary structure
- given a set of related RNA sequences, construct a model of the set
 - parameter learning (Inside-Outside)
 - structure refinement
- given a model of an RNA class, find sequences that belong to the class (Inside or CYK)
- given a sequence/structure, find other sequences with similar structure
- others not discussed
