Goals for Lecture

Key concepts:

- Markov Chain Monte Carlo (MCMC) and Gibbs sampling
- Gibbs sampling applied to the motif-finding task
- parameter tying
- incorporating prior knowledge using Dirichlets and Dirichlet mixtures

Gibbs Sampling: An Alternative to EM

- EM can get trapped in local maxima
- One approach to alleviate this limitation: try different (perhaps random) initial parameters
- Gibbs sampling exploits randomized search to a much greater degree
- Can view it as a stochastic analog of EM for this task
- In theory, Gibbs sampling is less susceptible to local maxima than EM
- [Lawrence et al., *Science* 1993]

Gibbs Sampling Approach

- In the EM approach we maintained a distribution $Z_i^{(t)}$ over the possible motif starting points for each sequence at iteration t
- In the Gibbs sampling approach, we'll maintain a **specific** starting point for each sequence a_i but we'll keep randomly resampling these

Gibbs Sampling Algorithm for Motif Finding

given: length parameter W , training set of sequences

choose random positions for a

do

pick a sequence X_i

estimate p given current motif positions a

(using all sequences but X_i) (predictive update step)

sample a new motif position a_i for X_i (sampling step)

until convergence

return: p, a

Markov Chain Monte Carlo (MCMC)

- Consider a Markov chain in which, on each time step, a grasshopper randomly chooses to stay in its current state, jump one state left or jump one state right.

Figure from Koller & Friedman, Probabilistic Graphical Models, MIT Press

- Let $P^{(t)}(u)$ represent the probability of being in state u at time t in the random walk

$$P^{(0)}(0) = 1$$

$$P^{(0)}(+1) = 0$$

$$P^{(0)}(+2) = 0$$

$$P^{(1)}(0) = 0.5$$

$$P^{(1)}(+1) = 0.25$$

$$P^{(1)}(+2) = 0$$

$$P^{(2)}(0) = 0.375$$

$$P^{(2)}(+1) = 0.25$$

$$P^{(2)}(+2) = 0.0625$$

$$\vdots$$
$$\vdots$$
$$\vdots$$

$$P^{(100)}(0) \approx 0.11$$

$$P^{(100)}(+1) \approx 0.11$$

$$P^{(100)}(+2) \approx 0.11$$

The Stationary Distribution

- Let $P(u)$ represent the probability of being in state u at any given time in a random walk on the chain

$$P^{(t)}(u) \approx P^{(t+1)}(u)$$

$$P^{(t+1)}(u) = \sum_v P^{(t)}(v) \tau(u | v)$$

probability of
state v

probability of
transition $v \rightarrow u$

- The stationary distribution is the set of such probabilities for all states

Markov Chain Monte Carlo (MCMC)

- We can view the motif finding approach in terms of a Markov chain
- Each state represents a configuration of the starting positions (a_i values for a set of random variables $A_1 \dots A_n$)
- Transitions correspond to changing selected starting positions (and hence moving to a new state)

state v

Markov Chain Monte Carlo

- In motif-finding task, the number of states is enormous
- Key idea: construct Markov chain with stationary distribution equal to distribution of interest; use sampling to find most probable states
- Detailed balance:

$$P(u)\tau(v | u) = P(v)\tau(u | v)$$

probability of state u

probability of transition $u \rightarrow v$

- When detailed balance holds:

$$\frac{1}{N} \lim_{N \rightarrow \infty} \text{count}(u) = P(u)$$

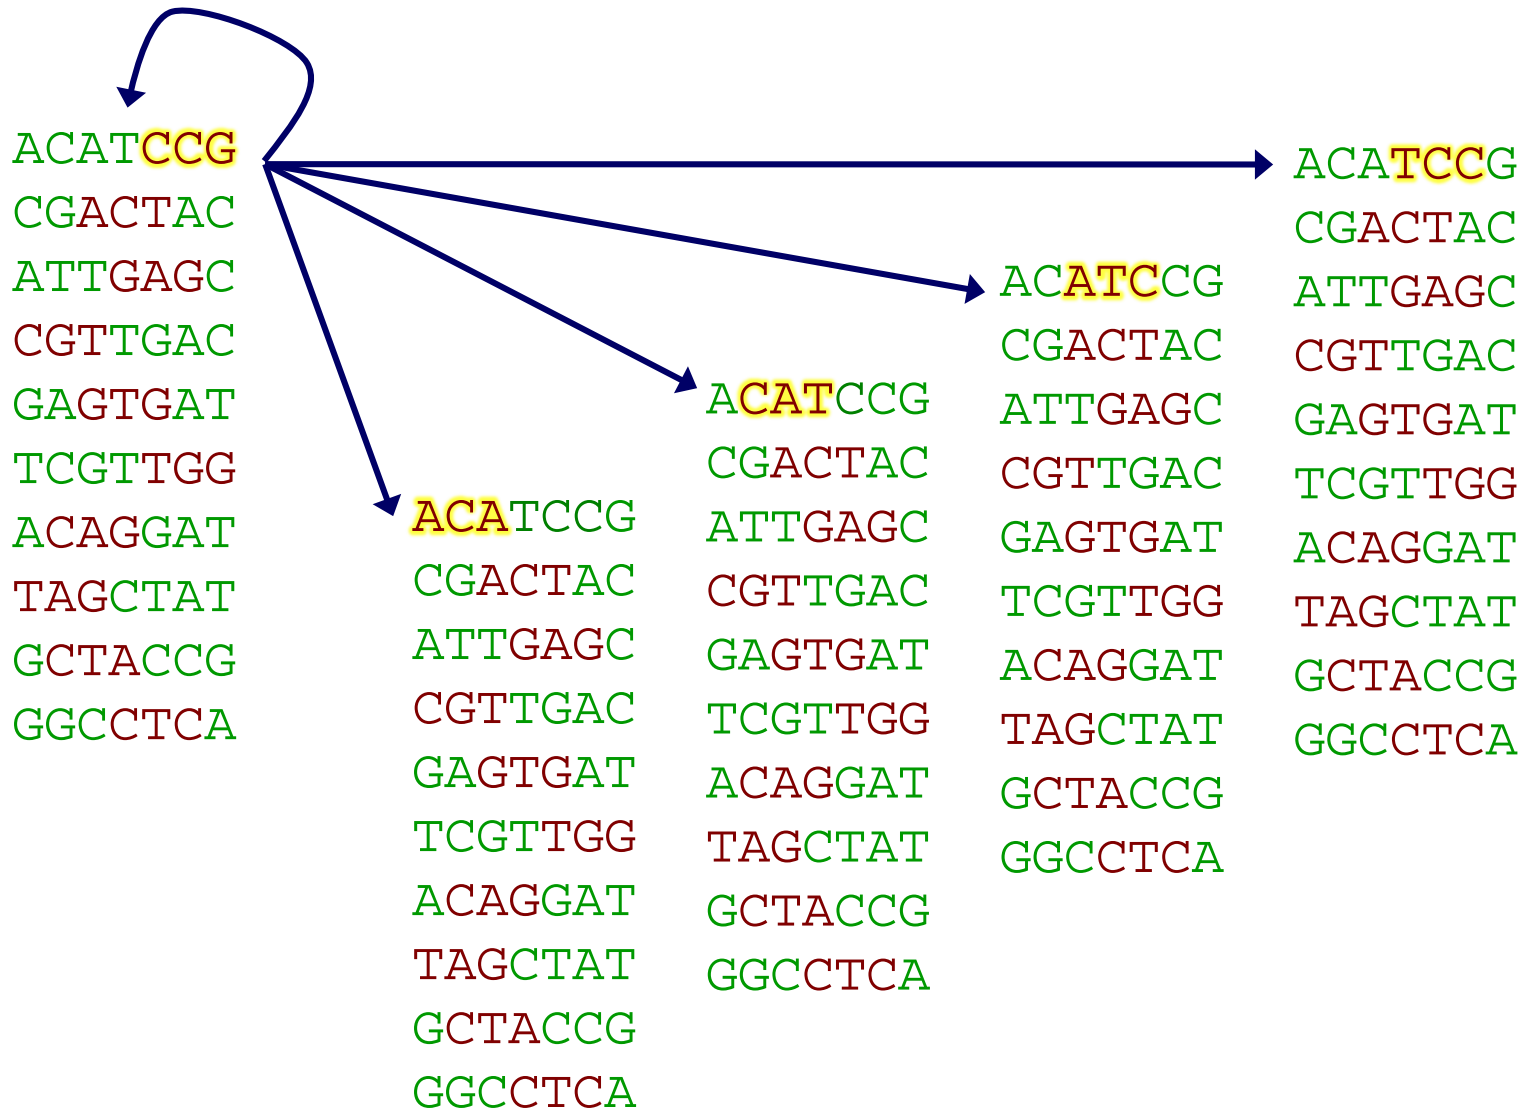

MCMC with Gibbs Sampling

Gibbs sampling is a special case of MCMC in which

- Markov chain transitions involve changing one variable at a time
- transition probability is conditional probability of the changed variable given all others
- i.e. we sample the joint distribution of a set of random variables $P(A_1 \dots A_n)$ by iteratively sampling from $P(A_i | A_1 \dots A_{i-1}, A_{i+1} \dots A_n)$

Gibbs Sampling Approach

- Possible state transitions when first sequence is selected

Gibbs Sampling Approach

- Lawrence et al. maximize the likelihood ratio

$$\frac{P(X | motif)}{P(X | background)}$$

- How do we get the transition probabilities when we don't know what the motif looks like?

Gibbs Sampling Approach

- The probability of a state is given by

$$P(u) \propto \prod_c \prod_{j=1}^W \left(\frac{p_{c,j}}{p_{c,0}} \right)^{n_{c,j}(u)}$$

background probability for character c

count of c in motif position j

probability of c in motif position j

u

A	1	3	1
C	5	2	1
G	2	2	6
T	2	3	2

See Liu et al., *JASA*, 1995
 for the full derivation

Sampling New Motif Positions

- For each possible starting position, $A_i = j$, compute the likelihood ratio (leaving sequence i out of estimates of p)

$$LR(j) = \frac{\prod_{k=j}^{j+W-1} P_{c_k, k-j+1}}{\prod_{k=j}^{j+W-1} P_{c_k, 0}}$$

- Randomly select a new starting position $A_i = j$ with probability

$$\frac{LR(j)}{\sum_{k \in \{\text{starting positions}\}} LR(k)}$$

The Phase Shift Problem

- Gibbs sampler can get stuck in a local maximum that corresponds to the correct solution shifted by a few bases
- Solution: add a special step to shift the a values by the same amount for all sequences
- Try different shift amounts and pick one in proportion to its probability score

Convergence of Gibbs

Using Background Knowledge to Bias the Parameters

Let's consider two ways in which background knowledge can be exploited in motif finding

1. Accounting for palindromes that are common in DNA binding sites
2. Using Dirichlet mixture priors to account for biochemical similarity of amino acids

Using Background Knowledge to Bias the Parameters

- Many DNA motifs have a palindromic pattern because they are bound by a protein *homodimer*: a complex consisting of two identical proteins

Representing Palindromes

- Parameters in probabilistic models can be “tied” or “shared”

- During motif search, try tying parameters according to palindromic constraint; accept if it increases likelihood ratio test (half as many parameters)

Updating Tied Parameters

$$p_{a,1} \equiv p_{t,W} = \frac{n_{a,1} + n_{t,W} + d_{a,1} + d_{t,W}}{\sum_b (n_{b,1} + d_{b,1}) + \sum_b (n_{b,W} + d_{b,W})}$$

Including Prior Knowledge

- Recall that the EM/Gibbs update the parameters by:

$$P_{c,k} = \frac{n_{c,k} + d_{c,k}}{\sum_b (n_{b,k} + d_{b,k})}$$

- Can we use background knowledge to guide our choice of pseudocounts ($d_{c,k}$)?
- Suppose we're modeling protein sequences...

Amino Acids

- Can we encode prior knowledge about amino acid properties into the motif finding process?
- There are classes of amino acids that share similar properties

Using Dirichlet Mixture Priors

- Because we're estimating multinomial distributions (frequencies of amino acids at each motif position), a natural way to encode prior knowledge is using Dirichlet distributions
- Let's consider
 - the Beta distribution
 - the Dirichlet distribution
 - mixtures of Dirichlets

The Beta Distribution

- Suppose we're taking a Bayesian approach to estimating the parameter θ of a weighted coin
- The Beta distribution provides an appropriate prior

$$P(\theta) = \frac{\Gamma(\alpha_h + \alpha_t)}{\Gamma(\alpha_h)\Gamma(\alpha_t)} \theta^{\alpha_h-1} (1-\theta)^{\alpha_t-1}$$

where

α_h # of “imaginary” heads we have seen already

α_t # of “imaginary” tails we have seen already

Γ continuous generalization of factorial function

0 Beta(1,1) 1

Beta(2,2)

Beta(3,2)

Beta(19,39)

The Beta Distribution

- Suppose now we're given a data set D in which we observe D_h heads and D_t tails

$$P(\theta | D) = \frac{\Gamma(\alpha + D_h + D_t)}{\Gamma(\alpha_h + D_h)\Gamma(\alpha_t + D_t)} \theta^{\alpha_h + D_h - 1} (1 - \theta)^{\alpha_t + D_t - 1}$$

$$= \mathbf{Beta}(\alpha_h + D_h, \alpha_t + D_t)$$

- The posterior distribution is also Beta: we say that the set of Beta distributions is a *conjugate* family for binomial sampling

The Dirichlet Distribution

- For discrete variables with more than two possible values, we can use *Dirichlet* priors
- Dirichlet priors are a *conjugate* family for multinomial data

$$P(\theta) = \frac{\Gamma\left(\sum_{i=1}^K \alpha_i\right)}{\prod_{i=1}^K \Gamma(\alpha_i)} \prod_{i=1}^K \theta_i^{\alpha_i - 1}$$

- If $P(\theta)$ is $\text{Dirichlet}(\alpha_1, \dots, \alpha_K)$, then $P(\theta|D)$ is $\text{Dirichlet}(\alpha_1 + D_1, \dots, \alpha_K + D_K)$, where D_i is the # occurrences of the i^{th} value

Dirichlet Distributions

Probability density (shown on a simplex) of Dirichlet distributions for $K=3$ and various parameter vectors α

$$\alpha = (6, 2, 2)$$

$$\alpha = (3, 7, 5)$$

$$\alpha = (2, 3, 4)$$

$$\alpha = (6, 2, 6)$$

Image from Wikipedia, MATLAB code by Peter Perkins

Mixture of Dirichlets

- We'd like to have Dirichlet distributions characterizing amino acids that tend to be used in certain “roles”
- Brown et al. [*ISMB '93*] induced a set of Dirichlets from “trusted” protein alignments
 - “large, charged and polar”
 - “polar and mostly negatively charged”
 - “hydrophobic, uncharged, nonpolar”
 - etc.

Trusted Protein Alignments

- A trusted protein alignment is one in which known protein structures are used to determine which parts of the given set of sequences should be aligned

Using Dirichlet *Mixture* Priors

- Recall that the EM/Gibbs update the parameters by:

$$p_{c,k} = \frac{n_{c,k} + d_{c,k}}{\sum_b (n_{b,k} + d_{b,k})}$$

- We can set the pseudocounts using a *mixture* of Dirichlets:

$$d_{c,k} = \sum_j P(\alpha^{(j)} | \mathbf{n}_k) \alpha_c^{(j)}$$

- where $\alpha^{(j)}$ is the j^{th} Dirichlet component

Using Dirichlet Mixture Priors

$$d_{c,k} = \sum_j P(\alpha^{(j)} | \mathbf{n}_k) \alpha_c^{(j)}$$

probability of j^{th} Dirichlet
given observed counts

parameter for character c
in j^{th} Dirichlet

- We don't have to know which Dirichlet to pick
- Instead, we'll hedge our bets, using the observed counts to decide how much to weight each Dirichlet

See textbook section 11.5

Motif Finding: EM and Gibbs

- These methods compute *local, multiple* alignments
- Optimize the likelihood or likelihood ratio of the sequences
- EM converges to a local maximum
- Gibbs will “converge” to a global maximum, *in the limit*; in a reasonable amount of time, probably not
- Can take advantage of background knowledge by
 - tying parameters
 - Dirichlet priors
- There are *many* other methods for motif finding
- In practice, motif finders often fail
 - motif “signal” may be weak
 - large search space, many local minima
 - do not consider binding context
